***Abstract*—In this paper, we consider the problem of state estimation through observations possibly corrupted with both bad data and additive observation noises. A mixed ℓ_1 and ℓ_2 convex programming is used to separate both sparse bad data and additive noises from the observations. Through using the almost Euclidean property for a linear subspace, we derive a new performance bound for the state estimation error under sparse bad data and additive observation noises. Our main contribution is to provide sharp bounds on the almost Euclidean property of a linear subspace, using the "escape-through-a-mesh" theorem from geometric functional analysis. We also propose and numerically evaluate an iterative convex programming approach to performing bad data detections in nonlinear electrical power networks problems.**

I. Introduction

In this paper, we study the problem of state estimation under both bad data and observation noise. In state estimation problems, the observations may be corrupted with abnormally large measurement errors, called bad data, in addition to the usual additive observation noise. More specifically, suppose we want to estate the state $\mathbf{x}$ described by an m-dimensional real-numbered vector, and we make n measurements, then these measurements can be written as an n-dimensional vector $\mathbf{y}$, which is related to the state vector through the measurement equation

$$\mathbf{y} = h(\mathbf{x}) + \mathbf{v} + \mathbf{e}, \tag{I.1}$$

where $h(\mathbf{x})$ is a nonlinear function relating the measurement vector to the state vector, and $\mathbf{v}$ is the vector of measurement noise, and $\mathbf{e}$ is the vector of bad data imposed on the measurement. In this paper, we assume that $\mathbf{v}$ is an m-dimensional vector with i.i.d. zero mean Gaussian elements of variance σ^2. We also assume that $\mathbf{e}$ is a vector with only k nonzero entries, and the nonzero entries can take arbitrary real-numbered values, reflecting the nature of bad data.

It is well known that Least Square (LS) method can be used to suppress the effect of observation noise on state estimations. In LS method, we try to find a vector $\mathbf{x}$ minimizing

$$\|\mathbf{y} - h(\mathbf{x})\|_2. \tag{I.2}$$

However, the LS method generally only works well when there are no bad data $\mathbf{e}$ corrupting the observation $\mathbf{y}$.

In this paper, a mixed least ℓ_1 norm and least square convex programming is used to simultaneously detect bad data and subtract additive noises from the observations. In our theoretical analysis of the decoding performance, we assume $h(\mathbf{x})$ is a linear transformation $H\mathbf{x}$ with H as an $n \times m$ matrix with i.i.d. standard zero mean Gaussian entries. Through using the almost Euclidean property for the linear subspace generated by H, we derive a new performance bound for the state estimation error under sparse bad data and additive observation noises. In our analysis, using the "escape-through-a-mesh" theorem from geometric functional analysis [5], we are able to significantly improve on the bounds for the almost Euclidean property of a linear subspace, which may be interesting in a more general mathematical setting. Compared with earlier analysis on the same optimization problem in [11], the analysis is new using the almost Euclidean property rather than the restricted isometry conditions used in [11], and we are able to give explicit bounds on the error performance, which is sharper than the analysis using the restricted isometry conditions in [11].

Inspired by bad data detection methods for linear systems, we further propose an iterative convex programming approach to perform combined bad data detection and denoising in nonlinear electrical power networks. The static state of an electric power network can be described by the vector of bus voltage magnitudes and angles in power networks. However, in smart grid power networks, the measurement of these quantities can be corrupted due to errors in the sensors, communication errors in transmitting the measurement results, and adversarial compromises of the meters. So the state estimation of power networks needs to detect, identify, and eliminate large measurement errors [1], [2], [3]. Since the probability of large measurement errors occurring is very small, it is reasonable to assume that bad data are only present in a small fraction of the available meter measurements results. So bad data detection in power networks can be viewed as a sparse error detection problem, which shares similar mathematical structures as sparse recoveries problem in compressive sensing [4], [11]. However, this problem in power networks has several unique properties when compared with ordinary sparse error detection problem [4]. In fact, $h(\mathbf{x})$ in (I.1) is a nonlinear mapping instead of a linear mapping in [11]. Our iterative convex programming based algorithms work is shown by numerical examples working well in this nonlinear setting. Compared with [12], which proposed to apply ℓ_1 minimization in bad data detection in power networks, our approach offers a better decoding error performance when both bad data and additive observation noises are present. [13][14] considered state estimations under malicious data attacks, and formulated the problem of state estimation under malicious attacks as a hypothesis testing problem by assuming a prior probability distribution on the state $\mathbf{x}$. In contrast, our approach does not rely on any prior information on the signal $\mathbf{x}$ itself, and the performance bounds hold for arbitrary state $\mathbf{x}$.

The rest of this paper is organized as follows. In Section

II, we introduce the convex programming to perform joint bad data detection and denoising, and derive the performance bound on the decoding error based on the almost Euclidean property of linear subspaces. In Section III, a sharp bound on the almost Euclidean property is given through the "escape-through-mesh" theorem. In Section IV, we will present explicit bounds on the decoding error. In Section V, we introduce our algorithm to perform bad data detection in nonlinear systems, and present simulation results of its performance in power networks.

II. Bad Data Detection for Linear Systems

In this section, we will introduce a convex programming formulation to do bad data detection in a linear systems, and give a characterization of its decoding error performance. In a linear system, the $n\times 1$ observation vector is $\mathbf{y} = H\mathbf{x}+\mathbf{e}+\mathbf{v}$, where $\mathbf{x}$ is the $m \times 1$ signal vector ($m < n$), $\mathbf{e}$ is a sparse error vector with k nonzero elements, $\mathbf{v}$ is a noise vector with $\|\mathbf{v}\|_2 \leq \epsilon$. In what follows, we denote the part of any vector $\mathbf{w}$ over any index set K' as $\mathbf{w}_{K'}$.

We solve the following optimization problem involving optimization variables $\mathbf{x}^*$ and $\mathbf{z}$, and we then estimate the state $\mathbf{x}$ to be $\hat{\mathbf{x}}$, which is the optimizing value for $\mathbf{x}^*$.

$$\begin{aligned} \min_{\mathbf{x}^*,\mathbf{z}} \quad & \|\mathbf{y} - H\mathbf{x}^* - \mathbf{z}\|_1, \\ \text{subject to} \quad & \|\mathbf{z}\|_2 \leq \epsilon. \end{aligned} \tag{II.1}$$

We are now ready to give the main theorem which bounds the decoding error performance of (II.1).

Theorem 2.1: Let $\mathbf{y}$, H, $\mathbf{x}$, $\mathbf{e}$ and $\mathbf{v}$ are specified as above. Suppose that the minimum nonzero singular value of H is $\sigma_{\min}$. Let C be a real number larger than 1, and suppose that every vector $\mathbf{w}$ in the subspace generated by the matrix H satisfies $C\|\mathbf{w}_K\|_1 \leq \|\mathbf{w}_{\overline{K}}\|_1$ for any subset $K \subseteq \{1, 2, ..., n\}$ with cardinality $|K| \leq k$, where k is an integer, and $\overline{K} = \{1, 2, ..., n\} \setminus K$. We also assume the subspace generated by H satisfies the *almost Euclidean* property for a constant $\alpha \leq 1$, namely

$$\alpha\sqrt{n}\|\mathbf{w}\|_2 \leq \|\mathbf{w}\|_1$$

holds for every $\mathbf{w}$ in the subspace generated by H

Then the solution $\hat{\mathbf{x}}$ satisfies

$$\|\mathbf{x} - \hat{\mathbf{x}}\|_2 \leq \frac{2(C+1)}{\sigma_{\min}\alpha(C-1)}\epsilon. \tag{II.2}$$

Proof: Suppose that one optimal solution set to (II.1) is $(\hat{\mathbf{x}}, \hat{\mathbf{z}})$. Since $\|z\|_2 \leq \epsilon$, we have $\|\hat{\mathbf{z}}\|_1 \leq \sqrt{n}\|\hat{\mathbf{z}}\|_2 \leq \sqrt{n}\epsilon$.

Since $\mathbf{x}^* = \mathbf{x}$ and $\mathbf{z} = \mathbf{v}$ is a feasible solution for (II.1), then

$$\begin{aligned} & \|\mathbf{y} - H\hat{\mathbf{x}} - \hat{\mathbf{z}}\|_1 \\ = \; & \|H(\mathbf{x} - \hat{\mathbf{x}}) + \mathbf{e} + \mathbf{v} - \hat{\mathbf{z}}\|_1 \\ \leq \; & \|H(\mathbf{x} - \mathbf{x}) + \mathbf{e} + \mathbf{v} - \mathbf{v}\|_1 \\ = \; & \|\mathbf{e}\|_1. \end{aligned}$$

Applying the triangle inequality to $\|H(x-\hat{\mathbf{x}})+\mathbf{e}+\mathbf{v}-\hat{\mathbf{z}}\|_1$, we further obtain

$$\|H(\mathbf{x} - \hat{\mathbf{x}}) + \mathbf{e}\|_1 - \|\mathbf{v}\|_1 - \|\hat{\mathbf{z}}\|_1 \leq \|\mathbf{e}\|_1.$$

Denoting $H(\mathbf{x} - \hat{\mathbf{x}})$ as $\mathbf{w}$, because $\mathbf{e}$ is supported on a set K with cardinality $|K| \leq k$, by the triangle inequality for ℓ_1 norm again,

$$\|\mathbf{e}\|_1 - \|\mathbf{w}_K\|_1 + \|\mathbf{w}_{\overline{K}}\|_1 - \|\mathbf{v}\|_1 - \|\hat{\mathbf{z}}\|_1 \leq \|\mathbf{e}\|_1.$$

So we have

$$-\|\mathbf{w}_K\|_1 + \|\mathbf{w}_{\overline{K}}\|_1 \leq \|\hat{\mathbf{z}}\|_1 + \|\mathbf{v}\|_1 \leq 2\sqrt{n}\epsilon \tag{II.3}$$

With $C\|\mathbf{w}_K\|_1 \leq \|\mathbf{w}_{\overline{K}}\|_1$, we know

$$\frac{C-1}{C+1}\|\mathbf{w}\|_1 \leq -\|\mathbf{w}_K\|_1 + \|\mathbf{w}_{\overline{K}}\|_1.$$

Combining this with (II.3), we obtain

$$\frac{C-1}{C+1}\|\mathbf{w}\|_1 \leq 2\sqrt{n}\epsilon.$$

By the almost Euclidean property $\alpha\sqrt{n}\|\mathbf{w}\|_2 \leq \|\mathbf{w}\|_1$, it follows:

$$\|\mathbf{w}\|_2 \leq \frac{2(C+1)}{\alpha(C-1)}\epsilon. \tag{II.4}$$

By the definition of singular values,

$$\sigma_{\min}\|\mathbf{x} - \hat{\mathbf{x}}\|_2 \leq \|H(\mathbf{x} - \hat{\mathbf{x}})\|_2 = \|\mathbf{w}\|_2, \tag{II.5}$$

so combining (II.4), we get

$$\|\mathbf{x} - \hat{\mathbf{x}}\|_2 \leq \frac{2(C+1)}{\sigma_{\min}\alpha(C-1)}\epsilon.$$

■

Note that when there are no sparse errors present, the decoding error bound satisfies $\|\mathbf{x} - \hat{\mathbf{x}}\|_2 \leq \frac{1}{\sigma_{\min}}\epsilon$, Theorem 2.1 shows that the decoding error of (II.1) is oblivious to the presence of bad data, no matter how large in amplitude these bad data can be. This phenomenon also observed in [11] by using the restricted isometry condition for compressive sensing.

We remark that, for given $\mathbf{y}$ and given ϵ, by strong lagrange duality theory, the solution $\hat{\mathbf{x}}$ to (II.1) will correspond to the solution to $\mathbf{x}$ in the following problem (II.6) for some Lagrange duality variable $\lambda \geq 0$. As $\epsilon \geq 0$ increases, the corresponding λ that produces the same solution to $\mathbf{x}$ will correspondingly decrease.

$$\min_{\mathbf{x},\mathbf{z}} \quad \|\mathbf{y} - H\mathbf{x} - \mathbf{z}\|_1 + \lambda\|\mathbf{z}\|_2. \tag{II.6}$$

In fact, when $\lambda \to \infty$, (II.6) approaches

$$\min_{\mathbf{x}} \quad \|\mathbf{y} - H\mathbf{x}\|_1,$$

and when $\lambda \to 0$, (II.6) approaches

$$\min_{\mathbf{x}} \quad \|\mathbf{y} - H\mathbf{x}\|_2.$$

Thus, (II.6) can be viewed as a weighed version of ℓ_1 minimization and ℓ_2 minimization (or equivalently the LS method). We will later use numerical experiments to show

that in order to recover a sparse vector from measurements with both noise and errors, this weighted version outperforms both ℓ_1 minimization and the LS method.

In the next two sections, we will aim at explicitly computing $\frac{2(C+1)}{\sigma_{\min}\alpha(C-1)} \times \sqrt{n}$, which will denote ϖ later in this paper. The appearance of the $\sqrt{n}$ factor is to compensate for the energy scaling of large random matrices and its meaning will be clear in later context. Next, we will compute explicitly the almost Euclidean property constant α.

III. Bounding the Almost Euclidean Property

In this section, we would like to give a quantitative bound on the almost Euclidean property constant α such that with high probability (with respect to the measure for the subspace generated by the random H), $\alpha\sqrt{n}\|\mathbf{w}\|_2 \leq \|\mathbf{w}\|_1$ holds for every vector $\mathbf{w}$ from the subspace generated by H. Here we assume that each element of H is generated from the standard Gaussian distribution $N(0,1)$. So the subspace generated by H is a uniformly distributed $(n-m)$-dimensional subspaces from the high dimensional geometry.

To ensure that the subspace generated from H satisfies the almost Euclidean property with $\alpha > 0$, we must have the event that the subspace generated by H does not intersect the set $\{\mathbf{w} \in S^{n-1} | \|\mathbf{w}\|_1 < \alpha\sqrt{n}\|\mathbf{w}\|_2\}$, where S^{n-1} is the Euclidean sphere in R^n. To evaluate the probability that this event happens, we will need the following "escape-through-mesh" theorem.

Theorem 3.1: [5] Let S be a subset of the unit Euclidean sphere S^{n-1} in R^n. Let Y be a random m-dimensional subspace of R^n, distributed uniformly in the Grassmanian with respect to the Haar measure. Let $w(S) = E(\sup_{\mathbf{w}\in S}(\mathbf{h}^T\mathbf{w}))$, where $\mathbf{h}$ is a random column vector in R^n with i.i.d. $N(0,1)$ components. Assume that $w(S) < (\sqrt{n-m} - \frac{1}{2\sqrt{n-m}})$. Then

$$P(Y \bigcap S = \emptyset) > 1 - 3.5e^{-\frac{(\sqrt{n-m}-\frac{1}{2\sqrt{n-m}})-w(S)}{18}}.$$

From Theorem 3.1, we can use the following programming to get an estimate of the upper bound of $w(\mathbf{h}, S)$. Because the set $\{\mathbf{w} \in S^{n-1} | \|\mathbf{w}\|_1 < \alpha\sqrt{n}\|\mathbf{w}\|_2\}$ is symmetric, without loss of generality, we assume that the elements of $\mathbf{h}$ follow i.i.d. half-normal distributions, namely the distribution for the absolute value of a standard zero mean Gaussian random variables. With h_i denoting the i-th element of $\mathbf{h}$, this is equivalent to

$$\max \quad \sum_{i=1}^{n} h_i y_i \tag{III.1}$$

$$\text{subject to} \quad y_0 \geq 0, 1 \leq i \leq n \tag{III.2}$$

$$\sum_{i=1}^{n} y_i \leq \alpha\sqrt{n} \tag{III.3}$$

$$\sum_{i=1}^{n} y_i^2 = 1. \tag{III.4}$$

Following the method from [7], we use the Lagrange duality to find an upper bound for the objective function of (III.1).

$$\min_{u_1\geq 0, u_2 \geq 0, \lambda \geq 0} \max_{w} \mathbf{h}^T\mathbf{w} - u_1(\sum_{i=1}^{n} w_i^2 - 1) \tag{III.5}$$

$$-u_2(\sum_{i=1}^{n} w_i - \alpha\sqrt{n}) + \sum_{i=1}^{n} \lambda_i w_i, \tag{III.6}$$

where λ is a vector $(\lambda_1, \lambda_2, ..., \lambda_n)$.

First, we maximize (III.6) over w_i, $i = 1, 2, ..., n$ for fixed u_1, u_2 and λ. By making the derivatives to be zero, the minimizing w_i is given by

$$w_i = \frac{h_i + \lambda_i - u_2}{2u_1}, 1 \leq i \leq n$$

Plugging this back, we get

$$\mathbf{h}^T\mathbf{w} - u_1(\sum_{i=1}^{n} w_i^2 - 1) \tag{III.7}$$

$$-u_2(\sum_{i=1}^{n} w_i - \alpha\sqrt{n}) + \sum_{i=1}^{n} \lambda_i w_i \tag{III.8}$$

$$= \frac{\sum_{i=1}^{n}(-u_2 + \lambda_i + h_i)^2}{4u_1} + u_1 + \alpha\sqrt{n}u_2. \tag{III.9}$$

Next, we minimize (III.9) over $u_1 \geq 0$. It is not hard to see the minimizing u_1^* is

$$u_1^* = \frac{\sqrt{\sum_{i=1}^{n}(-u_2 + \lambda_i + h_i)^2}}{2},$$

and the corresponding minimized value is

$$\sqrt{\sum_{i=1}^{n}(-u_2 + \lambda_i + h_i)^2} + \alpha\sqrt{n}u_2. \tag{III.10}$$

Then, we minimize (III.10) over $\lambda \geq 0$. Given $\mathbf{h}$ and $u_2 \geq 0$, it is easy to see that the minimizing λ is

$$\lambda_i = \begin{cases} u_2 - h_i & \text{if } h_i \leq u_2; \\ 0 & \text{otherwise,} \end{cases}$$

and the corresponding minimized value is

$$\sqrt{\sum_{1\leq i\leq n: h_i < u_2}(u_2 - h_i)^2} + \alpha\sqrt{n}u_2. \tag{III.11}$$

Now if we take any $u_2 \geq 0$, (III.11) serves as an upper bound for (III.6). Since $\sqrt{\cdot}$ is a concave function, by Jensen's inequality, we have for any given $u_2 \geq 0$,

$$E(\sup_{\mathbf{w}\in S}(\mathbf{h}^T w)) \leq \sqrt{E\{\sum_{1\leq i\leq n: h_i < u_2}(u_2 - h_i)^2\}} + \alpha\sqrt{n}u_2. \tag{III.12}$$

Since $\mathbf{h}$ has i.i.d. half-normal components, the righthand side of (III.12) equals to

$$(\sqrt{(u_2^2+1)\text{erfc}(u_2/\sqrt{2}) - \sqrt{2/\pi}u_2 e^{-u_2^2/2}} + \alpha u_2)\sqrt{n}, \tag{III.13}$$

where erfc is the error function.

One can check that (III.13) is convex in u_2. Given α, we

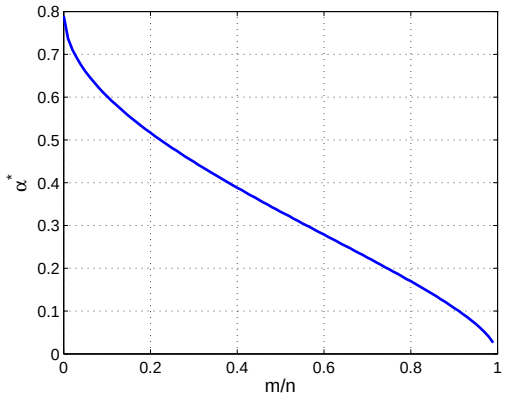

Fig. 1: α^* over m/n

minimize (III.13) over $u_2 \geq 0$ and let $g(\alpha)\sqrt{n}$ denote the minimum value. Then from (III.12) and (III.13) we know

$$w(S) = E(\sup_{\mathbf{w}\in S}(\mathbf{h}^T\mathbf{w})) \leq g(\alpha)\sqrt{n}. \qquad \text{(III.14)}$$

Given $\delta = \frac{m}{n}$, we pick the largest α^* such that $g(\alpha^*) < \sqrt{1-\delta}$. Then as n goes to infinity, it holds that

$$w(S) \leq g(\alpha^*)\sqrt{n} < (\sqrt{n-m} - \frac{1}{2\sqrt{n-m}}). \qquad \text{(III.15)}$$

Then from Theorem 3.1, with high probability $\|\mathbf{w}\|_1 \geq \alpha^*\sqrt{n}\|\mathbf{w}\|_2$ holds for every vector $\mathbf{w}$ in the subspace generated by H. We numerically calculate how α^* changes over δ and plot the curve in Fig. 1. For example, when $\delta = 0.5$, $\alpha^* = 0.332$, thus $\|\mathbf{w}\|_1 \geq 0.332\sqrt{n}\|\mathbf{w}\|_2$ for all $\mathbf{w}$ in the subspace generated by H.

Note that when $\frac{m}{n} = \frac{1}{2}$, we get $\alpha = 0.332$. That is much larger than the known α used in [15], which is approximately 0.07 (see Equation (12) in [15]). When applied to the sparse recovery problem considered in [15], we will be able to recover any vector with no more than $0.0289n = 0.0578m$ nonzero elements, which are 20 times more than the $\frac{1}{384}m$ bound in [15].

IV. Evaluating the Robust Error Correction Bound

If the elements in the measurement matrix H are i.i.d. as the unit real Gaussian random variables $N(0,1)$, following upon the work of Marchenko and Pastur [10], Geman[8] and Silverstein [9] proved that for $m/n = \delta$, as $n \to \infty$, the smallest nonzero singular value

$$\frac{1}{\sqrt{n}}\sigma_{\min} \to 1 - \sqrt{\delta}$$

almost surely as $n \to \infty$.

Now that we have already explicitly bounded α and $\sigma_{\min}$, we now proceed to characterize C. It turns out that our earlier result on the almost Euclidean property can be used to computed C.

Theorem 4.1: Suppose an n-dimensional vector $\mathbf{w}$ satisfies $\|\mathbf{w}\|_1 \geq \alpha\sqrt{n}\|\mathbf{w}\|_2$. Then if for some set $K \subseteq \{1,2,...,n\}$ with cardinality $|K| = k \leq n$,

$$\frac{\|\mathbf{w}_K\|_1}{\|\mathbf{w}\|_1} = \beta,$$

then β must be a number satisfying

$$\frac{\beta^2}{k} + \frac{(1-\beta)^2}{n-k} \leq \frac{1}{\alpha^2 n}$$

Proof: Without loss of generality, we let $\|\mathbf{w}\|_1 = 1$. Then by the Cauchy-Schwarz inequality,

$$\begin{aligned}\|\mathbf{w}\|_2^2 &= \|\mathbf{w}_K\|_2^2 + \|\mathbf{w}_{\overline{K}}\|_2^2 \\ &\geq (\frac{\|\mathbf{w}_K\|_1}{\sqrt{k}})^2 + (\frac{\|\mathbf{w}_{\overline{K}}\|_1}{\sqrt{n-k}})^2 \\ &= (\frac{\beta^2}{k} + \frac{(1-\beta)^2}{n-k})\|\mathbf{w}\|_1^2.\end{aligned}$$

At the same time, by the almost Euclidean property,

$$\alpha^2 n\|\mathbf{w}\|_2^2 \leq \|\mathbf{w}\|_1^2,$$

so we must have

$$\frac{\beta^2}{k} + \frac{(1-\beta)^2}{n-k} \leq \frac{1}{\alpha^2 n}$$

■

Corollary 4.2: If a nonzero n-dimensional vector $\mathbf{w}$ satisfies $\|\mathbf{w}\|_1 \geq \alpha\sqrt{n}\|\mathbf{w}\|_2$, and for any set $K \subseteq \{1,2,...,n\}$ with cardinality $|K| = k \leq n$, if $C\|\mathbf{w}_K\|_1 = \|\mathbf{w}_{\overline{K}}\|_1$ for some number $C \geq 1$, then

$$\frac{k}{n} \geq \frac{(B+1-C^2) - \sqrt{(B+1-C^2)^2 - 4B}}{2B}, \qquad \text{(IV.1)}$$

where $B = \frac{(C+1)^2}{\alpha^2}$.

Proof: If $C\|\mathbf{w}_K\|_1 \geq \|\mathbf{w}_{\overline{K}}\|_1$, we have

$$\frac{\|\mathbf{w}_K\|_1}{\|\mathbf{w}\|_1} = \frac{1}{C+1}.$$

So by Theorem 4.1, $\beta = \frac{1}{C+1}$ satisfies

$$\frac{\beta^2}{k} + \frac{(1-\beta)^2}{n-k} \leq \frac{1}{\alpha^2 n}.$$

This is equivalent to

$$\frac{1}{\frac{k}{n}} + \frac{C^2}{1-\frac{k}{n}} \leq \frac{(C+1)^2}{\alpha^2}$$

Solving this inequality for $\frac{k}{n}$, we get (IV.1).

■

So for a sparsity $\frac{k}{n}$, this corollary can be used to find C such that $\frac{\|\mathbf{w}_K\|_1}{\|\mathbf{w}\|_1} = \frac{1}{C+1}$. Combining these results on computing $\sigma_{\min}$, α and C, we can then compute the bound $\frac{2(C+1)}{\sigma_{\min}\alpha(C-1)}\sqrt{n} = \varpi$ in Theorem 2.1. For example, when $\delta = \frac{m}{n} = \frac{1}{2}$, we plot the bound ϖ as a function of $\frac{k}{n}$ in Fig. 2

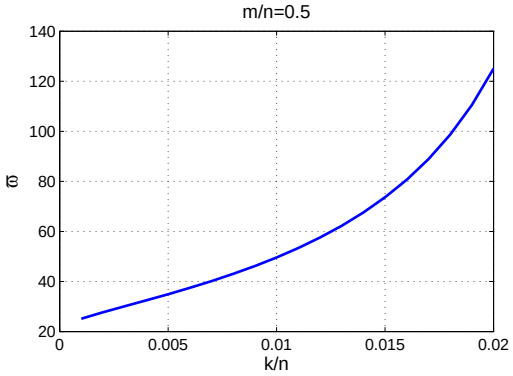

Fig. 2: ϖ versus $\frac{k}{n}$

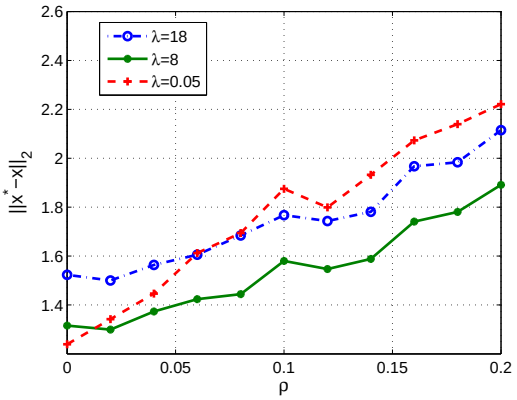

Fig. 4: λ^* versus ρ for Gaussian measurements

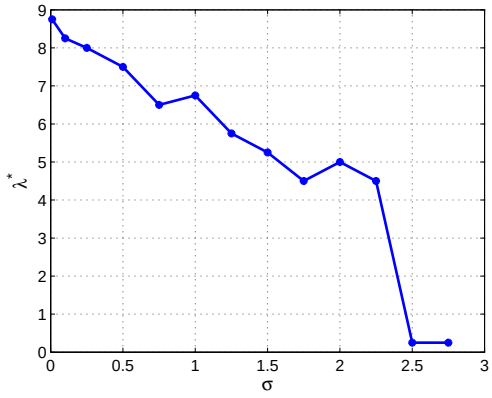

Fig. 3: λ^* versus σ for Gaussian measurements

V. Numerical Results

Experiment 1: We first consider recovering a signal vector from Gaussian measurements. We generate the measurement matrix $H^{n\times m}$ with i.i.d. $N(0,1)$ entries and a vector $\mathbf{x}' \in R^m$ with i.i.d Gaussian entries. Let $\mathbf{x} = \mathbf{x}'/\|\mathbf{x}'\|_2$ be the signal vector. Let $m = 60$ and $n = 150$. We first consider the recover performance when the number of erroneous measurements is fixed. We randomly choose twelve measurements and flip the signs of these measurements. For each measurement, we also independently add a Gaussian noise from $N(0,\sigma^2)$. For a given σ, we apply (II.6) to estimate $\mathbf{x}$ using λ from 0 to 13, and pick the best λ^* with which the estimation error is minimized. For each σ, the result is averaged over fifty runs. Fig. 3 shows the curve of λ^* against σ. When the number of measurements with bad data is fixed, λ^* decreases as the noise level increases.

We next fix the noise level and consider the estimation performance when the number of erroneous measurements changes. Each measurement has a Gaussian noise independently drawn from $N(0,0.5^2)$. Let ρ denote the percentage of erroneous measurements. Given ρ, we randomly choose ρn measurements, and each such measurement is added with a Gaussian error independently drawn from $N(0,5^2)$. The estimation result is averaged over fifty runs. Fig. 4 shows how the estimation error changes as ρ increases for different λ. $\lambda = 8$ has the best performance in this setup compared with a large value $\lambda = 15$ and a small value $\lambda = 0.05$.

Experiment 2: We also consider estimating the state of the power system from available measurements and known system configuration. The state variables are the voltage magnitudes and the voltage angles at each bus. The measurements can be the real and reactive power injections at each bus, and the real and reactive power flows on the lines. All the measurements are corrupted with noise, and a small fraction of the measurements contains errors. We would like to estimate the state variables from the corrupted measurements.

The relationship between the measurements and the state variables for a k'-bus system can be stated as follows [12]:

$$P_i = \sum_{j=1}^{k'} E_i E_j Y_{ij} \cos(\theta_{ij} + \delta_i - \delta_j), \quad \text{(V.1)}$$

$$Q_i = \sum_{j=1}^{k'} E_i E_j Y_{ij} \sin(\theta_{ij} + \delta_i - \delta_j), \quad \text{(V.2)}$$

$$P_{ij} = E_i E_j Y_{ij} \cos(\theta_{ij} + \delta_i - \delta_j) - E_i^2 Y_{ij} \cos\theta_{ij} + E_i^2 Y_{si} \cos\theta_{si} \quad i \neq j, \quad \text{(V.3)}$$

$$Q_{ij} = E_i E_j Y_{ij} \sin(\theta_{ij} + \delta_i - \delta_j) - E_i^2 Y_{ij} \sin\theta_{ij} + E_i^2 Y_{si} \sin\theta_{si} \quad i \neq j, \quad \text{(V.4)}$$

where P_i and Q_i are the real and reactive power injection at bus i respectively, P_{ij} and Q_{ij} are the real and reactive power flow from bus i to bus j, E_i and δ_i are the voltage magnitude and angle at bus i. Y_{ij} and θ_{ij} are the magnitude and phase angle of admittance from bus i to bus j, Y_{si} and θ_{si} are the magnitude and angle of the shunt admittance of line at bus i. Given a power system, all Y_{ij}, θ_{ij}, Y_{si} and θ_{si} are known.

For a k'-bus system, we treat one bus as the reference bus and set the voltage angle at the reference bus to be zero. There are $m = 2k' - 1$ state variables with the first k' variables for

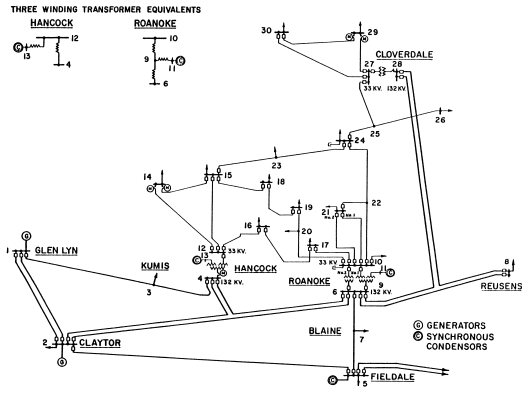

Fig. 5: IEEE 30-bus test system

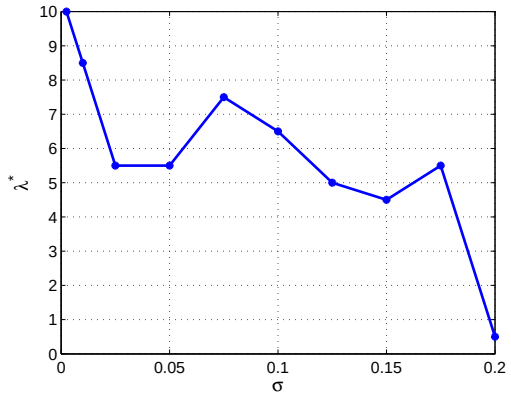

Fig. 6: λ^* versus σ

the bus voltage magnitudes E_i and the rest $k'-1$ variables for the bus voltage angles θ_i. Let $\mathbf{x} \in R^m$ denote the state variables and let $\mathbf{y} \in R^n$ denote the n measurements of the real and reactive power injection and power flow. Let $\mathbf{v} \in R^n$ denote the noise and $\mathbf{e} \in R^n$ denote the sparse error vector. Then we can write the equations in a compact form,

$$\mathbf{y} = h(\mathbf{x}) + \mathbf{v} + \mathbf{e}, \tag{V.5}$$

where $h(\cdot)$ denotes n nonlinear functions defined in (V.1) to (V.4).

An estimate of the state variables, $\hat{\mathbf{x}}$, can be obtained by solving the following minimization problem,

$$\min_{\mathbf{x},\mathbf{z}} \quad \|\mathbf{y} - h(\mathbf{x}) - \mathbf{z}\|_1 + \lambda\|\mathbf{z}\|_2, \tag{V.6}$$

where $\hat{\mathbf{x}}$ is the optimal solution $\mathbf{x}$. $\lambda > 0$ is a fixed parameter. When $\lambda \to \infty$, (V.6) approaches

$$\min_{\mathbf{x}} \quad \|\mathbf{y} - h(\mathbf{x})\|_1, \tag{V.7}$$

and when $\lambda \to 0$, (V.6) approaches

$$\min_{\mathbf{x}} \quad \|\mathbf{y} - h(\mathbf{x})\|_2. \tag{V.8}$$

Since h is nonlinear, we linearize the equations and apply an iterative procedure to obtain a solution. We start with the initial state $\mathbf{x}^0$ where $x_i^0 = 1$ for all $i \in \{1, ..., n\}$, and $x_i^0 = 0$ for all $i \in \{n+1, ..., 2n-1\}$. In the kth iteration, let $\Delta\mathbf{y}^k = \mathbf{y} - h(\mathbf{x}^{k-1})$, then we solve the following convex optimization problem,

$$\min_{\Delta\mathbf{x},\mathbf{z}} \quad \|\Delta\mathbf{y}^k - H\Delta\mathbf{x} - \mathbf{z}\|_1 + \lambda\|\mathbf{z}\|_2, \tag{V.9}$$

where $H^{n\times m}$ is the Jacobian matrix of h evaluated at $\mathbf{x}^{k-1}$. Let $\Delta\mathbf{x}^k$ denote the optimal solution $\Delta\mathbf{x}$ to (V.9), then the state estimation is updated by

$$\mathbf{x}^k = \mathbf{x}^{k-1} + \Delta\mathbf{x}^k. \tag{V.10}$$

We repeat the process until $\Delta\mathbf{x}^k \to 0$.

We evaluate the performance on the IEEE 30-bus test system. Fig. 5 shows the structure of the test system. Then the state vector contains fifty-nine variables. We take one hundred measurement including the real and reactive power injection at each bus and some of the real and reactive power flows on the lines. We first consider how the estimation performance changes as the noise level increases when the erroneous measurements are fixed. The errors of the measurements are simulated by inverting the sign of the real power injection at bus 2, bus 3, bus 5, bus 26 and bus 30, and inverting the sign of the reactive power injection at bus 30. Each measurement also contains a Gaussian noise independently drawn from $N(0, \sigma^2)$. For a fixed noise level σ, we solve (V.6) by the iterative procedure using different λ (from 0.5 to 12). The estimation performance is measured by $\|\mathbf{x}^* - \hat{\mathbf{x}}\|_2$, where $\mathbf{x}^*$ is the true state variable and $\hat{\mathbf{x}}$ is our estimation. For a fixed σ, we choose the λ^* to be the one with which $\|\mathbf{x}^* - \hat{\mathbf{x}}\|_2$ is minimal among all the λ's we consider. The result is averaged over fifty runs. Fig. 6 shows how λ^* changes as σ increases from 0 to 0.2. When the noise level is low, i.e. the measurements basically only contain errors, then the estimation performance is better when we use a larger λ. When the noise level is high, a smaller λ leads to a better performance.

We also study how the estimation performance changes as the number of erroneous measurements increases. Each of the one hundred measurements contains random Gaussian noise independently drawn from $N(0, 0.05^2)$. Let ρ denote the percentage of erroneous measurements with bad data. For fixed ρ, we randomly choose the set T of erroneous measurements with cardinality $|T| = \rho m$. Each erroneous measurement contains an additional Gaussian error independently drawn from $N(0, 0.7^2)$. We than calculate the solution $\hat{\mathbf{x}}$ of (V.6) and the estimation error $\|\mathbf{x}^* - \hat{\mathbf{x}}\|_2$. Fig. 7 shows how the estimation error changes as ρ increases. The results are averaged over fifty runs. When λ is small ($\lambda = 0.5$), (V.6) approaches (V.7), and the estimation error is relatively large if ρ is small, i.e. the measurements basically contain only noise. When λ is large ($\lambda = 12$), (V.6) approaches (V.8), and the estimation error is relatively large if ρ is large, i.e. the measurements contains errors besides noise. In contrast, if we choose λ to be 7 in this case, the estimation error is relatively small for all ρ among the three choices of λ.

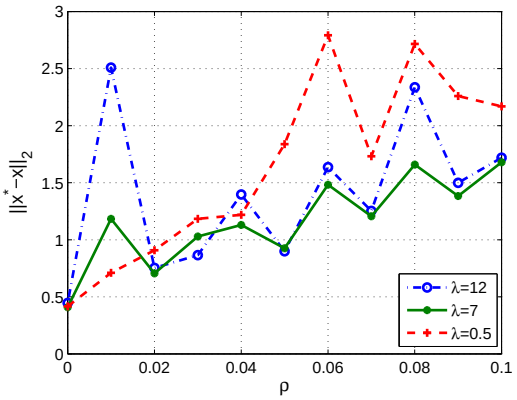

Fig. 7: The estimation error versus ρ

VI. Conclusion

In this paper, we study state estimation through observations corrupted with both bad data and additive observation noises. A mixed ℓ_1 and ℓ_2 convex programming is used to separate both sparse bad data and additive noises from the observations. We used the almost Euclidean property of a linear subspace to provide sharp bounds on this convex programming based state estimation method. We also give sharp bounds for the almost Euclidean property of a linear subspace using the "escape-through-a-mesh" theorem from geometric functional analysis [5]. We then propose an iterative convex programming based methods to perform state estimation with bad data detection in the nonlinear electrical power network problems. Simulation results confirm the effectiveness of the algorithms in denoising and detecting bad data at the same time.
